

Please do not upload this copyright pdf document to any other website. Breach of copyright may result in a criminal conviction.

This pdf document was generated by me Colin Hinson from a Crown copyright document held at R.A.F. Henlow Signals Museum. It is presented here (for free) under the Open Government Licence (O.G.L.) and this pdf version of the document is my copyright (along with the Crown Copyright) in much the same way as a photograph would be.

The document should have been downloaded from my website <https://blunham.com/Radar>, or any mirror site named on that site. If you downloaded it from elsewhere, please let me know (particularly if you were charged for it). You can contact me via my Genuki email page: <https://www.genuki.org.uk/big/eng/YKS/various?recipient=colin>

You may not copy the file for onward transmission of the data nor attempt to make monetary gain by the use of these files. If you want someone else to have a copy of the file, point them at the website. (<https://blunham.com/Radar>). Please do not point them at the file itself as it may move or the site may be updated.

It should be noted that most of the pages are identifiable as having been processed by me.

I put a lot of time into producing these files which is why you are met with this page when you open the file.

In order to generate this file, I need to scan the pages, split the double pages and remove any edge marks such as punch holes, clean up the pages, set the relevant pages to be all the same size and alignment. I then run Omnipage (OCR) to generate the searchable text and then generate the pdf file.

Hopefully after all that, I end up with a presentable file. If you find missing pages, pages in the wrong order, anything else wrong with the file or simply want to make a comment, please drop me a line (see above).

It is my hope that you find the file of use to you personally – I know that I would have liked to have found some of these files years ago – they would have saved me a lot of time !

SECTION 1

GENERAL DESCRIPTION AND SPECIFICATION

1. 1 GENERAL

The colour television monitor type ET9954 is suitable for monochrome or colour and employs a 19" reinforced shadow mask CRT of the latest design. Performance features and overall design make this instrument suitable for all the high quality requirements of broadcasting studios and outside broadcast installations.

Versions are available for standard 19" rack mounting or as cased units for mounting on control desks. The monitor is suitable for either 625-line CCIR or 525-line EIA systems, with simple adjustment of the appropriate controls on a pull out front drawer unit. Decoders for PAL or NTSC system working may be supplied with the monitor.

Provision is made for the front panel signal selector facility to be controlled at a remote point. The push button selector is for three inputs:

1. R. G. B.,
2. Test.
3. Coded Signal.

In addition to the above the normal controls are provided on the front panel for Contrast, Brightness, On/Off with Indicator Lamp selection (for camera or ON AIR), together with a mode switch for individual selection of Red, Blue, Green, Black/White, colour.

All the important setting-up controls are mounted on a pull-out front drawer unit for ease of adjustment.

Mains supply facilities cater for 100-117V or 220-234V with a ±10% tolerance of input at 48-62 Hz.

1. 2 SPECIFICATION

1. Dimensions

	<u>19 inch</u>		<u>25 inch</u>
	<u>Rack</u>	<u>Case</u>	<u>Case version only</u>
Height:	21.2 in (530 mm)	22.2 in (555 mm)	25.4 in (635 mm)
Width:	17.7 in (444 mm)	18.9 in (481 mm)	24.2 in (605 mm)
Depth:	22.2 in (540 mm)	24.0 in (600 mm)	24.8 in (620 mm)

2. Weight

- 120 lb. 55 kg. approx. (19" version)
209 lb. 94 kg. (25" version)

3. Mains Supply

110V-117V or 220V-234V ±10%
48 to 62 Hz

Failure of the mains fuses is indicated by means of neon lamps on the rear panel. The supply frequency may differ from the nominal field frequency of the system in use.

4. Power

440 watts nominal.

5. Systems

625 lines 50 Hz - CCIR
525 lines 60 Hz - EIA

Operation on either standard may be obtained by adjustment of front drawer controls.

6. Line Time Base

Horizontal hold is maintained over a minimum range of 60° rotation of the hold control.

The pull-in range is at least ±300 Hz
The hold-in range is at least ±1 kHz

7. Field Time Base

Vertical hold is maintained over a minimum range of 60° rotation of the hold control which has sufficient range to pull in on either of the line standards.

8. Interlace

55.45

9. Aspect Ratio

Masked to 4:3

10. Inputs

Provision is made for the following inputs:

- (a) R, G and B Video with or without the addition of mixed syncs at a video level between 0.35V and 1.5V p-p positive.

- (b) Separate Sync input negative going with an amplitude between 0.5V and 6V p-p. A modification for positive going sync is available if requested, at extra cost.
- (c) Coded Input. Composite Colour Signal (625 PAL or 525 NTSC) 0.5V to 2V p-p positive going.
- (d) Test Input. Positive video with or without mixed syncs at a video level between 0.35V and 1.5V p-p.

Two BNC sockets and a switch are provided on all channels for looped or terminated operation. Terminating resistors are $75\Omega \pm 1\%$.

11. Input Characteristics

The input circuit is a high impedance bridging type having an effective shunt impedance not worse than $35k\Omega$ in shunt with $10pF$, whether power is applied to the monitor or not.

The addition of 50% mains hum to the signal will not cause significant deterioration of the picture.

12. Frequency Response

Within ± 0.5 dB to 5 MHz) with respect to 1 MHz measured
Less than 3 dB down at 8 MHz) with CRT drive of 30V p-p

13. Grey Scale Tracking

The R, G, B gains and black level settings may be adjusted so that with a staircase test signal applied equally to the R, G and B inputs, difference in chromaticity between steps are less than the equivalent of 2% of peak white at the input.

14. Contrast

One master control is provided on the front panel, together with a balance control in each channel. The master control may be set to give the specified luminance from input signals within the stated range and is capable of reducing the output substantially to zero.

15. Black Level Clamps

The monitor employs feedback black level clamps. Variations in the black levels of the CRT red, green and blue drive signals due to each of the following are not worse than $\pm 0.5V$:

- (a) Picture content
- (b) Signal composite or non-composite
- (c) Power supply ripple
- (d) Mains supply variations

(e) Sync pulse parameters within their tolerances.

In addition the differences in black level of any pair of CRT signals change by not more than 0.25V.

16. EHT

The EHT is 25 kV nominal with an output impedance of less than 300k Ω .

17. Luminance

The monitor, including the loss due to the protective screen, is capable of giving a luminance on a plain white (illuminance colour 6500 $^{\circ}$ k) raster occupying half the picture area of not less than 880 nits without perceptible defocussing. A master brightness control is provided on the front panel, together with separate black level controls for each gun.

18. Linearity and Geometry

The intersection of the grid pattern lines is within 2% diameter circles of the projected test pattern in areas A and B of the drawing provided.

19. Positional Hum

Displacement of the raster due to magnetic fields generated within the equipment is less than 0.1% of picture height.

20. Amplitude Hum

Luminance modulation due to hum voltages is invisible on a uniform grey background under any viewing conditions with R, G, B inputs bridged.

21. Stability

Operation to specification may be obtained (by adjustment) within the ambient temperature range -10 $^{\circ}$ C to +45 $^{\circ}$ C, and without adjustment over any 10 $^{\circ}$ C within the range -10 $^{\circ}$ C to +45 $^{\circ}$ C.

22. Earth System

The monitor has a fully floating technical earth system, and provision is made to connect external and local earth wires.

23. Flyback Suppression

Both line and field flyback suppression are provided so that flyback lines are not visible on the CRT under any normal viewing conditions.

24. Flyback Times

Flyback times for field and line scans are not greater than 1mS and 10.5 μ S respectively.

25. Scan Amplitudes

Both timebases are capable of 5% overscan. The scan controls are capable of adjusting the raster from the overscan position to a position where the four corners of the raster are visible.

26. Sweep Failure

A means is provided to protect the CRT from screen-burning in the event of vertical and/or horizontal deflection circuit failure, or in the event of disconnection of the scan coil plug.

27. Purity

When individual adjustments have been made for optimum colour purity, a plain field of any of the three primary colours or any combination of them is free from significant colour contamination.

28. Convergence

With respect to Areas A, B and C of the drawing provided, the spatial displacement between any two colour components of a single input signal is not greater than the fraction of active line length specified below:

Area A	1/750
Area B	1/500
Area C	1/375

29. Automatic Degaussing

Degaussing coils are incorporated which operate each time the monitor is switched on.

30. Controls

The following controls are provided on the front panel with unrestricted access:

Mains Switch and Indicator Lamp

Contrast

Brightness

		<u>Front Panel Text</u>
Input Selector Switch -	1. R, G, B	RGB
	2. Test	Test
	3. Coded	Code
Mode Switch	- 1. Red Gun ON 2. Blue Gun ON 3. Green Gun ON 4. Black/White 5. Colour	R B G Y C

'Camera' and 'On-Air' Indicator lamps.

Controls for the adjustment of the following are available within the front drawer unit:

- 1. R, G, B Brightness
- 2. Focus
- 3. Int/Ext Sync Selector
- 4. System Switch
- 5. Picture Size Switch
- 6. Width
- 7. Height
- 8. Horizontal DC Shift
- 9. Vertical DC Shift
- 10. Line Convergence
- 11. Field Convergence
- 12. Static Convergence
- 13. R, G, B Gain
- 14. Line Hold
- 15. Field Hold
- 16. Field Linearity
- 17. Purity
- 18. Pincushion

The following facilities are provided at the rear:

Ians input plug (Philips Type 5722 660 20880)

Mains Fuses and Indicator Neons

Mains Voltage Selectors

DC Power Supply Fuses

BNC Coaxial Sockets and Loop/Terminate switches fitted to a removable panel (50Ω BNC type UG 1094/U).

Separate Earth Terminals
Indicator Lamp (fixed socket)
Remote Control (fixed plug) for input selector

Remote selection of the three input signal groups RGB, Test, and Coded, requires that all three buttons of the input selector switch are released.

1.3 MECHANICAL DATA

In order to assist servicing and maintenance, the monitor is divided into four major units, with the optional decoder as a fifth item.

1. The Power Supply unit is fitted on sliding runners at the rear of the monitor and may be withdrawn after the removal of two captive screws. A.C. and D.C. fuses, and mains transformer tap adjustments are accessible at the back of the unit. All monitor supplies (except E.H.T.) are available in this assembly, including those for the fan and for degaussing.
2. The High Voltage and Line Output Unit consists of two separate sub-assemblies individually mounted on the monitor rear panel. This panel hinges down for inspection and servicing. Each sub-assembly is also hinged in order to provide access to the copper side of the printed circuit boards.
3. The Front Drawer unit contains most of the low level electronic circuitry together with the cue and designation indicators. The front panel of this unit carries the operational controls as listed in the specification.

For setting up and servicing the complete unit may be withdrawn on its sliding runners. All the controls needed for routine adjustments are provided on the top of this unit and are identified by titling on the perspex cover plate.

4. The Main Frame contains the Cathode Ray Tube with the blanking and field output stages. The convergence unit and the three video output assemblies are on plug-in printed circuit boards. Two coil assemblies are provided - one for normal deflection purposes, and the other for convergence, purity, and blue lateral shift. The degaussing coils are also in this unit. No magnets are used for any picture adjustment. To ease the tube changing procedure, both the principal coil assemblies are connected by plugs and sockets.
5. When the Decoder unit is provided, this is found as a plug-in printed circuit module on the right-hand side at the rear of the monitor.

SECTION 2

TECHNICAL DESCRIPTION

2.1 GENERAL

The monitor accepts either Standard RGB colour signals with the added sync pulses, (VBS input) or the sync signals can be separately supplied (VB + S input). When required the monitor may be fitted with a decoder unit to accept a composite colour signal (CVBS input).

A separate test signal input can be accepted. In this condition the RGB amplifier inputs are connected in parallel to give a monochrome picture. All the inputs are provided with two sockets to permit bridging through of the signals or can be terminated with 75Ω resistors by the individual switches.

Versions are available for the 625-line PAL or the 525-line NTSC systems.

The input signal condition is selected by three push buttons on the front panel for R.G.B., Test, or Coded signals.

A second row of push buttons allows the mode of the display to be chosen, i.e. full colour, one only or two only of the primary colours (red, green and blue), or monochrome. For the latter condition the R.G.B. signals applied to the input sockets, or supplied from the Decoder Unit, are mixed to provide a luminance signal made up of 30% red, 59% green and 11% blue. This signal is fed to the three video amplifiers. The 'colour killer' circuit is also automatically operated when the monochrome condition is selected.

The video amplifiers (see Video Amplifier and Video Output Circuits) employ feedback clamp circuits which stabilise the black level at the Cathode of the Cathode Ray Tube. Grey Scale tracking is achieved by individual gain controls and also by control of the three screen (G2) potentials. The contrast control comprises a 23-position ganged switch with associated close-tolerance resistors. Brightness (master black level) adjustment is obtained by variation of a line frequency pulse which is added at equal levels to the red, green and blue video channel signals.

The Decoder unit circuits for both the PAL (625-line) and NTSC (525-line) versions are of a similar form. Each includes a crystal controlled subcarrier reference generator, balanced transistor demodulator, a 12 dB subcarrier notch circuit, together with the virtual-earth matrix amplifiers. The decoder makes use of the monitors synchronising separator circuit signals and feeds out at low impedance of version of the incoming video for synchronising purposes. The PAL version employs a glass delay line,

together with sum and difference amplifiers prior to demodulation. Conversion to PAL or NTSC decoding is easily achieved, and the Decoder Unit plugs in at the rear of the monitor. The Decoder Units are designed for highly stable operation over the full performance range. Internal adjustments of Control Chroma Gain and Hue are intended only for initial setting up.

The EHT supply circuits - see Line and EHT Output circuit diagram - provide a 25 kV highly stabilised output. Stabilisation is provided against both fluctuations in the load requirements and in the supply. Circuit arrangements also give protection against any damage which might otherwise result from a failure of operation of the line scanning circuits, and also from the accidental disconnection of the scanning coil.

The line and field deflection circuits are stabilised to give constant amplitude outputs. Overall design also ensures negligible geometric distortion, together with highly efficient electronic pincushion correction (see Field Scan and Pincushion Assembly circuit). A picture size switch is provided to cater for both normal monitor other display functions. Focus supply voltage for the electrostatic focus potential to the CRT is derived from the rectified flyback pulses of the line output stage. Such valves as are employed are protected during the warm-up period by a delay which holds off the screen supply for about one minute.

With the exception of the axial shift of the deflector coils, all convergence and purity adjustments are catered for by the controls within the front drawer unit. All the necessary sawtooth, parabola and other waveforms produced by the normal active circuits are then matrixed by virtual-earth amplifiers for convenience in adjustment when a grid test pattern is employed in setting up. Static convergence is obtained by d.c. being added to the dynamic correction which is applied to the field convergence coils. Picture shift is effected by means of d.c. current in the scan coils.

A pair of degaussing coils positioned around the cone of the C.R.T. are activated automatically for a short period each time the monitor is switched on. The degaussing prevents the shadow mask and any other steel assemblies in the vicinity of C.R.T. being gradually magnetised by parasitic magnetic fields and hence giving rise to distortion.

The monitor has a fully floating 'technical-earth' system and provision is made for connection of the external and local earth leads. A blower unit is incorporated together an air filter to exclude dust, and also a thermal cut-out. These latter provisions are designed to ensure adequate cooling under a variety of ambient conditions, but are in fact only essential in applications where higher than normal temperatures are encountered. The thermal cut-out operates only under exceptional conditions, e.g. where unusual fault conditions raise the internal temperature of the monitor to a dangerous level.

2.2 INPUT AND MATRIX PWB MODULE - CIRCUIT 0175

The purpose of this Printed Wiring Board Module is to select the required video from the three available inputs, i.e. RGB, TEST or CODE, and also to provide a true 'Y' signal for displaying a black/white picture. The desired output is fed out to the master contrast control.

The R, G and B inputs from the monitor input panel are fed into emitter follower stages TS259, TS260 and TS261. The test input and the RGB decoder outputs are similarly fed to TS258 (TEST) and TS251, TS252 and TS253 (Decode).

RGB, TEST or CODE are selected by switching the gating diodes and the base emitter junction of the particular source required. The inputs which are not selected have their base emitter junctions reverse biased.

The d.c. control voltages used are +24V or 0V, which are selected by the 3-button switch on the front panel. These same voltages are also used to select the appropriate sync source by operating relays on the Sync Processing Module - circuit 0463.

The RGB outputs from the emitter followers are fed to the Colour/Mono gating diodes, GR252-GR254-GR256 or GR261-GR266-GR268 and also through the matrix resistors R256-R261-R266 or R296-R297-R305 to the emitter of the grounded base stage TS254.

This circuitry effects the summing of the correct proportions of R, G, B delivered by the matrix resistors at the emitter of TS254.

The voltage gain of TS254 is arranged such that the output voltage at the collector is $Y = 0.3R + 0.59G + 0.11B$. This Y signal is fed via the emitter follower TS262 to the Colour/Mono gating diodes GR257-GR258-GR259; these diodes are biased on or off by the voltage (0V or 24V) obtained via the resistors R280-R281-R282 from the Mono push button on the front panel.

The output of the Colour/Mono gate is fed to the base of the emitter followers TS255-TS256 and TS257, the outputs of which are fed to the master contrast control on the front panel. The output of the Green channel is also taken via R314 to the Sync PWB where it forms an input for the sync separator on sync processing module 0463. See Section 2.5.

2.3 VIDEO AMPLIFIER PWB MODULE - CIRCUIT 0176

The Printed Wiring Board Module contains three identical low-level video amplifier circuits - Red, Green and Blue.

It receives three inputs from the contrast control on the front panel, and after the addition of a brightness pulse and the required d.c. level, the outputs are fed via coaxial cables to the video output PWBs - see Section 2.4.

Gain controls are fitted to each channel and these are accessible in the front drawer for setting up the desired white level.

The input is terminated at high frequency in 75Ω by C385 and R423; it is then amplified by the d.c. coupled pair TS367 and TS369. The gain control is R401 and the positive going brightness pulse is added to the video signal after the sync pulse via R397.

The amplitude of the brightness pulse is the same for all three amplifiers and is controlled by the brightness control on the front panel of the monitor.

The tip of this pulse is clamped to a d.c. level fed back from the video output circuit, such that the d.c. level at the cathode of the CRT is 95V. The clamp transistor is TS371 and it is switched on by a positive going clamp pulse from the sync circuit fed in via R405 and C376.

2.4 VIDEO OUTPUT - CIRCUIT 0183

The output is fed to the video output via the common collector stages TS373 and TS374. The video output stages are shown on circuit 0183 and employ fairly conventional solid state circuitry.

2.5 SYNC PROCESSING MODULE - CIRCUIT 0463

External Sync

External sync input is fed to the base of TS451 which for standard negative sync performs as an emitter follower. A link in the emitter circuit is provided to preset for the required range of input level, either 0.5V p-p - 3V p-p. or 1.5V p-p - 6V p-p.

If it is required to work on positive-going external sync, the link across R456 should be removed and connected across R454 and the link from RLA changed from the emitter to the collector circuit of TS451.

Sync Amplifier and Separator

The appropriate sync signal as selected and programmed by the RGB, TEST and CODE buttons on the front panel is fed to the base of the sync amplifier TS452.

The collector of TS452 feeds a feedback type of low pass filter incorporating TS454 which limits the rise time of pulses to approx 0.4 μ S and serves to remove noise and subcarrier from the sync signal.

The signal from the emitter of TS454 is a.c. coupled to the base of the sync separator transistor TS456, where it is d.c. restored on the tips of pulses. TS456 conducts during the sync pulse period, giving rise to negative going sync pulses at its collector.

During the conduction period part of the base current of TS456 is provided by the collector of TS455. This has the effect of reducing the amount of sync pulse absorbed by the base current and reducing variations in clipping level with the 'weight' of the video signal.

To improve the performance of the sync separator when the monitor is used with certain types of video tape recorders, a feedback system is incorporated to the base of TS456 which has the effect of lengthening the base time constant in the absence of line pulses during the field sync period.

The composite sync output from the sync separator is taken via the emitter follower TS457. An additional emitter follower TS458 feeds composite sync to the decoder module, when fitted.

Phase Splitter and Decoder Delay

Transistors TS460 and TS461 operate as a long tailed clipper pair which provide a 'window' near the centre of the composite sync waveform applied to the base of TS460.

Positive pulses are developed at the collector of TS460 and negative pulses at the collector of TS461.

Positive pulses are developed at the collector of TS460 and negative pulses at the collector of TS461.

To allow for the delay in the decoder, when the CODE button is pressed TS459 is made to conduct and thus apply C465 across the base resistor of TS460 giving rise to a delay of approx $0.5\mu\text{s}$ to the pulses at the collectors of TS460 and TS461.

Brightness Pulse Generator

Positive going sync pulses are fed from the collector of TS460 via a short-time-constant coupling to the base of TS462. Since TS462 is normally conducting with the collector bottomed, the collector current is unaffected by the leading edge of a pulse.

In the presence of a differentiated back edge to the pulse, the collector current will be switched off for a period determined by the time constant of the base circuit giving rise to a positive pulse of voltage at the collector, the leading edge of which corresponds to the back edge of the initiating sync pulse.

The output from the collector of TS462 is fed to the base of TS479 which is normally non-conducting. In the presence of a pulse on its base TS479 conducts and produces a negative going pulse at its collector, the amplitude of which is determined by the voltage across C496.

The amplitude of brightness pulse can therefore be varied by adjusting the d.c. voltage across C496 by means of the brightness control or over a smaller range by the remote brightness control.

Transistor TS480 serves as an emitter follower to distribute the brightness pulses to the video amplifiers.

Clamp Pulse Generator

The operation of TS465 is similar to that of TS462 associated with the brightness pulse circuit.

In this case, however, the base resistors R505 and R507 are taken to a d.c. voltage which is developed by rectification of the sync pulses appearing at the collector of TS461. By this means the clamp transistors on the video amplifiers are maintained in conduction in the absence of input syncs so that the d.c. loop is kept constant.

The clamp pulses appearing at the collector of TS465 are fed via the emitter follower TS466 to the video amplifiers.

Field Sync Separator

The composite sync signal appearing at the emitter of TS457 is fed to the base of TS463.

In the collector circuit of TS463 is a lumped parameter open-circuit delay line which produces a reflection of the pulses developed across R501 by the collector current.

The delay is such that a reflected line pulse occurs after the finish of the initiating pulse. In the case of the wide field pulses, however, the reflected pulses build up on top of the initiating pulses, thereby producing double amplitude field pulses.

Separation of the field pulses is effected by arranging the bias of TS464 so that conduction occurs only on the double-amplitude pulses.

Line Flywheel

Negative going mixed sync is fed from the collector of TS461 through a short-time-constant coupling to the base of TS467.

The negative going spike produced at the base of TS467 by a sync pulse leading edge causes it to conduct and ring the damped tuned circuit in its collector.

The first negative going half cycle of the damped oscillation train produced at the collectors of TS467 causes TS468 to conduct, giving rise to a positive going pulse at its collector which is delayed relative to the initiating sync pulse.

In order to suppress half line pulses, a differentiated pulse is fed from TS468 collector to the base of TS569, causing TS569 to be switched off for a period determined by the time constant of C478 and R518.

A positive going pulse is thereby produced at the collector of TS469, the width of which exceeds half a line period. This pulse is fed back to the base of TS468 to hold it in a non-conducting condition during the half line pulse period.

Line pulses are fed from the collector of TS468 to the emitter coupled pair of transistors TS470 and TS471, giving rise to negative going pulses at the collector of TS471.

In the presence of a line pulse the diodes GR463 and GR464 conduct permitting C482 and C483 to assume a charge dependant on the relative phasing of the pulse compared with a sawtooth waveform generated from the line scan to which the common diode point is referred.

A control voltage is thus developed and applied via the emitter followers TS472 and TS473 to the base resistors of the multivibrator pair TS474 and TS475 which drives the line scan unit.

The reference sawtooth for the phase comparator is developed by feeding a line flyback pulse to the pulse shaping transistor TS476 which then drives a miller integrator incorporating TS475 to provide the sawtooth.

A variable d.c. component of voltage is added to the sawtooth by means of the hold control potentiometer T553.

Field Scan

Field sync pulses are fed to the field multivibrator TS552 and TS553 via the emitter follower TS554.

The field hold control is R558 and 60 Hz field operation when required is obtained by switching R559 with 50/60 Hz system switch on the right-hand side of the front drawer.

TS551 feeds the field flyback blanking pulse to the CRT base PWB module (see Section 2.11). During flyback TS553 discharges C558 and C559 via GR557, R564 and L551. During scan C558 and C559 charge via the constant current source TS555 and the bootstrap feedback from TS557.

The sawtooth voltage developed across C558 and C559 is fed to the transformer coupled output stage via the emitter followers TS556 and TS557.

Control of scan amplitude is obtained by adjusting the voltage on TS555 base by means of R576 (large scan and R577 small scan). Correction for 60 Hz operation is obtained by switching R569 and resetting the emitter potential of TS555.

Non-symmetrical linearity correction is obtained by the feedback from TS557 and is adjusted by R580.

Symmetrical 'S' correction is obtained by integrating a sawtooth voltage which is proportional to field scan, obtained from a resistance in series with the scan coils and using the resultant parabola to modulate the constant current charging source TS555. 'S' correction may be adjusted by R558 for optimum.

Pincushion Correction

This circuit produces the current waveform in the field deflector coil windings necessary to correct for the field component of pincushion distortion.

Transistors TS560 and TS562 form an emitter coupled pair, the emitter current for which is provided by the collector current of TS561. Transistor TS560 is normally conducting TS562 is cut off. Negative going line pulses are applied to the base of TS560 so that during the presence of each line pulse TS560 is cut off and the collector current of TS561 passes through TS562.

Transistors TS563, TS565 and TS566 have a similar configuration to TS560, TS562, and TS561 described above. Since TS560 and TS565 have a common collector load and TS560 is conducting when TS565 is off and vice

versa, then during the presence of a line pulse a current determined by TS564 flows via TS565 into the collector load. During the remainder of the line period the current in the common collector load is determined by the current of TS561 flowing via TS560.

A frame sawtooth of positive polarity is applied to the base of TS564 which is emitter coupled to TS561. The field sawtooth of current appearing in the collector of TS561 is therefore of opposite polarity to that appearing in the collector of TS564. The relative amplitudes are adjusted to be equal to the mark/space ratio of the line drive pulse by means of R613.

The collector current waveform of TS560 is a train of line pulses with a sawtooth modulation at field frequency and having minimum amplitude at the start of the field sawtooth. The collector current of TS565 is also a train of line pulses modulated at field frequency, but having in this case maximum amplitude at the start of the field sawtooth waveform.

The sum of the collector currents of TS560 and TS565 produces positive pulses of maximum amplitude at the start of each field scan, decreasing linearly to zero at the centre of the field period. They then reverse in polarity and increase linearly to a maximum at the end of the field scan.

The output currents from the collectors of TS560 and TS562 drive the cascode miller integrator circuit comprising TS566 and TS567 which produces at the collector of TS566 a "bow tie" waveform composed of line sawtooth modulated at field frequency.

Transistors TS568 and TS569 are emitter followers which serve to drive the field output emitter follower TS926. The field deflector coils are transformer coupled to TS926 emitter - see circuit 0167.

Line non-symmetry of the pincushion current waveform due to losses in the output stage has been compensated for by the introduction of R626 and C583 in the collector of TS567.

2.7 FIELD AND STATIC CONVERGENCE MODULE - CIRCUIT 0180

The static and field frequency components of the currents required by the convergence coils are generated in this unit. The amplitude controls of the Red/Green dynamic currents are matrixed for ease of adjustment.

Transistor TS752 is incorporated in a miller integrator stage. A field sawtooth from the field scan generator applied to the input of the stage gives rise to a parabolic voltage of field frequency at the collector of TS752. This parabolic voltage is fed via the emitter follower TS753 to the Red, Green, Blue and Blue lateral output amplifiers and also to the line scan generator to provide horizontal pincushion correction.

The sawtooth drive is also fed to the emitter coupled pair of transistors TS754 and TS755 to produce sawtooth waveforms of equal amplitude but of opposite polarity at their collectors. Potentiometers R787-R790 enable sawtooth waveforms of adjustable amplitude and polarity to be applied to the Red, Green, Blue and Blue lateral output amplifiers. TS756 is a phase inverter which enables the Red/Green sawtooth components to be matrixed in such a way as to provide maximum simplicity of adjustment.

The Red, Green and Blue output amplifiers are of identical configuration. The Red output amplifier comprises transistors TS757, TS758, TS759 and TS760. Transistors TS757 and TS758 are a complementary pair which feed the convergence coil from their common collectors. The Blue output amplifier comprises transistors TS761, TS762, TS763 and TS764, and Green amplifier TS765 to TS768.

2.8 LINE OUTPUT AND E.H.T. MODULES - CIRCUIT 0170

2.8.2 Line Output and Auxiliary Circuits

Line drive is fed via the coupling capacitor C1151 to the grid of the driver stage B1151a. The output waveform is shaped by C1154 and R1156 and is fed to the output valve B1152 via C1155. DC bias from the control loop is fed to the grid via R1160.

Transformer T1151, Efficiency Diode B1153, together with the boost capacitor C1175, C1161, form an energy recovery line scan generator, the scan coils being connected across Terminals 8 and 5.

An underscan facility is available by switching in L1152 in series with the scan coils, the switch being located in the front drawer of the monitor.

C1166 tunes the system to give a flyback time of approximately $10\mu S$, and its value is reduced by switching in C1172 in the underscan position in series with C1166.

'S' correction is obtained by the action of the boost capacitors C1175 and C1161, and correction in the underscan position is achieved by switching in parallel C1164 across C1161.

The primary of T1152 is placed in series with the scan coils and the sawtooth voltage across the secondary is fed out to the Line Convergence PWB module - see circuit 0179.

Linearity Circuit

The flyback pulse developed across a winding on the transformer T1151 is rectified by GR1160 and GR1161. The resultant d.c. current charges the capacitors C1178, C1179 and C1180. During the scan period the charge on these capacitors modifies the HT line voltage to achieve the required linearity.

C1181 and R1194 form a clamping network across the linearity winding and C1177, C1176, R1191 and R1190 clamp the width reduction coil L1152.

Damping circuits are fitted to both sides of the scan coils, these being GR1152, R1169, R1168, C1165, GR1156, R1174 and C1167.

±600V Supply

A positive going flyback pulse is taken from Pin 8 on T1151, a.c. coupled through C1174 DC restored by GR1157 and rectified by GR1155. The reservoir capacitor is C1168, and the filter components are R1176, C1201 and C1203.

A flyback pulse is taken from Pins 2 and 3 via R1172 to the Sync processing module (circuit 0463) for use in the line flywheel circuit.

Focus Supply

The positive going pulse appearing at the anode of B1152 is rectified by GR1152 and the resulting d.c. across the reservoir capacitor C1170 is applied to potential divider chain R1180-R1186. The focus potentiometer is part of this chain.

The focus control is situated in the front drawer unit, and the output to the focus electrode is taken from the slider of this control (R1254).

DC Shift

The d.c. component of the cathode current of the output valve B1152 is arranged to flow via the centre tapped shift control, R1256 in the front drawer unit, then through the scan coil unit in a direction dependant on the control setting with respect to the control position.

Width Control

Positive going pulses from Pin 8 on T1151 are fed to a potential divider C1156-C1157-C1158 and then to the anode of the controlled triode rectifier B1151b, where the resulting d.c. forms the bias voltage of the output valve B1152.

The efficiency of rectification and therefore the bias, depends on the grid-cathode voltage of B1151b, and this is determined by the output voltage of the cathode follower B1202a and on the setting of the width control R1255.

Pincushion Correction

The voltage at the cathode of B1202a is determined by the reference neon B1201, plus an added field frequency parabola voltage derived from the Field Convergence PWB module (see circuit 0180).

The line scan amplitude is therefore modulated at field frequency with its amplitude and shape dependant on the incoming waveforms.

+240V Supply

A stabilised supply is used to feed the valve screens and the driver stages in the Line and EHT units. This is derived from a conventional series stabiliser B1204, difference amplifier B1202b and neon reference B1203.

The divider chain R1209-R1208 and R1207 samples the output and the final output voltage is set by R1208. The +350V supply to the anode of B1204 is obtained from the Power Supply unit and the voltage dependant resistor R1216 presents an excessive voltage output if B1202 is removed.

2.8.3 E.H.T. and Beam Current Limit

Line drive is applied via C1001 to the grid of the cathode follower B1001a the output of which is fed to the grid of the driver pentode B1002a.

From the anode of B1002a, the drive waveform is shaped by R1006 and C1005 and is fed to the grid of the output pentode via C1998 and grid stopper R1018.

DC bias from the feedback loop is fed in via R1015 and zener diode GR1001 prevents excessive voltage appearing across R1019 in any fault conditions or during the warm-up period.

The EHT transformer T1001 and efficiency diode B1005 form an energy recovery system together with boost capacitor C1017.

The flyback pulse is rectified by B1006 and forms the approx 25kV EHT output.

A bleed resistor R1021 ensures the discharge of the CRT capacitance after switch off to provide protection during servicing.

A pulse obtained from a winding on T1 is fed via C1016 to the peak rectifier system GR1004-GR1002-GR1005-C1021-C1022, the output of which drives the cathode follower B1002b.

A proportion of the d.c. voltage at the emitter of B1002a, determined by R1031 (the SET EHT control) is applied through R1027 to the grid of B1001b, the cathode potential of which is determined by the reference voltage of neon B1003 and by the divider chain R1013-R1012.

Pulses are also obtained from the divider chain C1009-C1010-C1011, which are applied to the anode of B1001b. This valve acts as a half wave rectifier whose d.c. output depends not only on the input pulse but also on its grid cathode voltage determined as described above.

This d.c. voltage forms the control bias for the output valve and is fed into the grid via R1015.

Provision is made to feed in a large negative voltage via R1016 from the Line Scan unit. This voltage appears on failure of the line scan circuitry and ensures that burning of the screen cannot occur under scan failure conditions since the E.H.T. is removed.

The feedback system described above stabilises the output pulses under no load conditions, but current feedback is required to keep the EHT constant under varying load conditions. This feedback is applied by arranging the EHT output current to flow through R1024 and R1025. The d.c. voltage drop across R1026-R1025 is arranged to add to the d.c. error voltage applied to the grid of B1002b.

The amount of compensation applied is adjusted by R1024, the SET EHT REGULATION control.

The +240V stabilised supply to the EHT and line unit is switched on by the relay RE1200. This relay is controlled in turn by TS1055 and TS1057 in the +24V supply line to ensure that low voltage supplies are made before E.H.T. can be established. Additional protection is provided as follows:

- (a) TS1055 is switched on after a time delay (80 secs) determined by R1066 charging C1056 and C1057 by the F.E.T. TS1056.
- (b) TS1057 is switched on by a field scan waveform fed into the amplifier stages TS1051-TS1052. The output is integrated on C1054 and fed to the base of TS1057.

Beam Current Limit

It is necessary to limit the mean beam current flowing in the CRT to $250\mu\text{A}$ (19") or 1mA for 25". This is achieved by the Beam Current Limit circuit TS1001-TS1002.

The voltage at the cathode of B1004 is proportional to the EHT current and is used to operate the BCL circuit by switching off TS1001 at a current level set by T1039. TS1001 is d.c. coupled by the zener diode GR1008 and R1042-R1043 to TS1002. This transistor is turned off and its collector voltage goes negative towards a potential set by R1044-R1045.

This negative voltage is fed to the grids of the CRT via the 5-button push switch on the front panel.

The potential divider R1040-R1041 supplies -150V to the 5-button push switch where it is switched to the required CRT grids to obtain cut off when a given colour selection is needed for setting up.

The negative voltage supplying the potential divider R1040-R1041 is obtained from the rectifier and smoothing circuit GR1202-GR1201-C1204 which is fed from the mains transformer to the Power Supply Unit module - see circuit 0169.

2.9 LINE CONVERGENCE MODULE - CIRCUIT 0179

The line frequency components of the currents required by the convergence coils are produced by this unit in conjunction with the Line Convergence Output Module - see Section 2.10 and circuit 0373.

A sawtooth of voltage is developed across a small resistor in series with the line scan coils and is transformer coupled to the base circuit of TS651 via connector pin 9.

The sawtooth waveform which appears at the collector of TS651 is of equal voltage but opposite polarity to that which appears at the emitter.

Potentiometers R658, R665 and R670 connected between collectors and emitter enable sawtooth waveforms of adjustable amplitude and polarity to be produced for driving the Blue, Blue lateral, Red and Green line convergence output stages. The phase splitter TS652 enables the controls R665 and R670 to provide common and differential adjustment respectively of the red and green sawtooth amplitudes.

Transistor TS653 is driven from the emitter of TS651 and the transmitter functions as a miller integrator to produce a parabolic waveform at its collector.

The output from the miller integrator is fed to TS654 which produces a parabolic waveform at its collector in opposite phase to that produced at its emitter. The red and green parabola components are fed from the emitter circuit of TS654. The potentiometer R691 varies the amplitude of red and green together, and R702 provides a differential adjustment.

The collector circuit of TS654 feeds the blue output stage. Since the waveform required for good blue convergence is not truly parabolic, a correction is applied by means of a biased diode circuit in the emitter of TS654, this has the effect of steepening the sides of the parabolic waveform appearing at the collector.

The blue lateral output stage, which may require either polarity of the parabola waveform, is driven from a potentiometer connected across collector and emitter of TS654.

The various sawtooth and parabolic outputs from this unit are added and fed to the input of their respective output stages by means of series resistors since the output stages require a current drive.

To provide correction for relative horizontal trapezium distortion between the red and green rasters, a 'bow-tie' waveform composed of line sawtooth modulated waveforms at field frequency is fed into the base circuit of TS652 from the field pincushion corrector.

A constant current of adjustable amplitude and polarity to the Static Blue Lateral coils is provided by means of a complementary pair of transistors TS655 and TS656, the common collectors of which feed the coils. Adjustment of R705 produces a differential current in the transistors which flows into the coils.

Similar circuits are used incorporating TS657 and TS658 for driving the Purity coil 'X' and TS659 and TS660 for driving purity coil 'Y'.

2.10 LINE CONVERGENCE OUTPUT MODULE - CIRCUIT 0373

Blue Convergence

The blue signal from the line convergence module is applied via connector A, Pin 10 to the base circuit of TS851.

The amplified signal at the collector of TS851 is applied via the emitter followers TS852 and TS855 to the push-pull output stage comprising TS853, TS854, TS856 and TS857.

At normal signal level the output stage is approaching 'Class B' operation and to avoid distortion of the waveform feedback is applied from a resistor R879 in series with the blue convergence coils via the phase inverter TS869 to the base of TS851.

The negative feedback gives rise to a low impedance at the base circuit of TS851, therefore the input signal is applied in the form of current drive.

In order to stabilise the mean potential of the common collectors of the output stage, d.c. feedback is applied from their collectors to the bases of TS852 and TS855.

The convergence coil is damped by means of C859 and R878 to prevent spurious ringing waveforms.

The high frequency response characteristic which is essential to prevent instability is determined by C853 and R942.

Red Convergence

The red signal from the line convergence module is applied via Connector A, Pin 5 to the base of TS858. Amplification of the signal is effected by TS858 which drives the push-pull output stage comprising TS859 and TS860 from its collector circuit.

Negative feedback is applied from the emitters of TS859 and TS860 to the base of TS858 in order to prevent distortion of the waveform at the output.

DC feedback from the collectors to the bases of TS859 and TS860 serves to stabilise their mean collector potential.

Green Convergence

This circuit is similar to that used for Red Convergence and the same circuit techniques are employed - see circuit diagram 0373.

Blue Lateral

The blue signal from the line convergence unit is applied via connector A, Pin 14 to the base of TS864.

The amplified signal at the collector of TS864 is applied via the emitter followers TS865 and TS866 to the push-pull output stage comprising TS868 and TS867.

Negative feedback is applied from the emitters of TS868 and TS867 to the base of TS864 in order to ensure the correct and undistorted signals.

The mean collector potential of TS868 and TS867 is stabilised by means of d.c. feedback from their collector circuits to the bases of TS865 and TS866.

2.11 MAIN FRAME ASSEMBLY - CIRCUIT 0167

2.11.1 C.R.T. Potentials and Flashover Protection

Field and line blanking pulses are fed to the base of TS975 and the resultant composite blanking waveform is a.c. coupled, d.c. restored and applied to the R, G and B grids of the C.R.T.

The diodes GR978-GR979-GR980 clamp to the potential present on the capacitors C983-C984 and C985. This potential is 0V for normal operation, but may be taken to -150V via R995-R994 and R993 and the R, G and B selector buttons on the front panel when colour selection is needed for setting up or servicing.

A negative potential is also applied on operation of the beam current limiter circuit which operates to suit the size of C.R.T. employed.

The negative potentials are derived from the -300V supply in the line output unit - see circuit 0170.

Video drive is applied from the video output PWB module (circuit 0183) via wander plugs and leads direct to the R, G and B cathodes. R979-R980 and R981 limit the current flow should C.R.T. flashover occur under fault conditions, and hence the voltage developed back in the video circuits.

The A1 supply is derived from the R, G and B brightness controls in the monitor front drawer, and after decoupling by R976-R977 (blue) is applied via the current limiting resistors R996-R997-R998 to the A1 electrodes of the CRT.

The brightness controls are supplied with +600V generated in the line scan output unit - see circuit 0170.

The focus supply (5 kV) is also derived in the line scan output unit and fed to the focus control in the front drawer. The output from this control is then decoupled by R978 and C978 (on centre chassis) and fed via a current limiting resistor R999 to the focus electrode.

All electrodes are protected from the effects of external flashover of the CRT by spark gaps and by current limiting resistors.

2.11.2 Centre Chassis and Main Frame Assembly

Mounted on this panel are the field output and pincushion output stages together with the edge connectors for the video output PWB modules.

The field output transistor TS927 is driven by the emitter follower on the field scan module, and the output is auto-transformed and capacity coupled to the field scan coils. A voltage proportional to scan current is developed across R928.

The vertical pincushion output emitter follower TS926 is coupled to the primary of T926, the secondary of which is again in series with the field scan coils.

DC shift is applied via R927 and R929.

The degaussing coils are plugged into a 4-pole socket on the centre chassis, also the deflection coil assembly. The convergence output module is located at the top of the main frame and the field convergence socket on the centre chassis.

Provision is made for the decoder module to plug in on the right hand side of the main frame when the unit is supplied.

The indicator lamps on the front panel may be energised from either an internal 6.3V power source, Pins 1 and 5, or from an external supply direct to Pins 2, 3 and 4 on the indicator plug on the main frame rear panel.

On this panel will also be found the remote control socket for use in studio and similar installations. This allows the remote control of signal source selection and brightness of simple/delay for the PAL system, also the coaxial input sockets and 75Ω termination switches.

2.12 POWER SUPPLY UNIT MODULE - CIRCUIT 0169

The following supplies are derived from transformer T2:

- +30V Unstabilised, obtained from GR107-GR110, C7, and is fed via fuse VL101 to the vertical pincushion correction circuits.
- +24V Stabilised, derived from the +30V via a conventional series stabiliser circuit.

TS1 is the series element driven by TS151; the difference amplifier TS153, TS152 forms a constant current source and GR154-155-156 the reference potential.

TS154 is used for over current protection and operates to reduce the output when an excessive voltage drop occurs across R159-R162.

The feedback voltage is taken from the +24V bussbar on the centre chassis to reduce the effective output impedance .

- +12V Stabilised, obtained from GR111-GR114-C8, and is fed via the series stabiliser circuit similar to the +24V mentioned above.
- +6V Is obtained from the +12V supply via R183 and R184 and feeds the CRT heater (0.9A).

Zener diode GK161 protects the CRT heater from over volt damage.

T1 secondaries also supply the 6.3V a.c. for the valve heaters in the line units and the E.H.T. unit.

The degaussing coils are in series with the a.c. input to a bridge rectifier GR102-GR103, whose output charges C2. The leakage current of C2 and the current through R101 flows via GR101, GR106 and R102 and the a.c. current in the degaussing coils is rapidly reduced to zero. C2 rapidly discharges when the monitor is off so that the degaussing facility is immediately available when switching on.

Transformer T1 provides the medium voltages: +400V unstabilised from rectifier GR51, 2 x +270V unstabilised outputs from bridge rectifier GR52-GR55, 300V via the 100mA fuse YL51, and +130V from the bridge rectifier GR56-GR59 via the 200mA fuse YL6.

The transformer primaries are protected by fuses and by a thermal trip device which operates if severe overheating occurs. Fuses are fitted to suit the voltage source in use i.e. 3.15A for 220-240V or 6.3A for 110-107V supply.

SECTION 3

MAINTENANCE

GENERAL

The normal precautions should be taken in servicing the semiconductor modules. Thermal shunts should always be employed when disconnecting semiconductor devices, or when replacing these. Care must be taken to avoid short circuiting biassing components. The monitor should be switched off during replacement of any components to avoid dangerous voltage surges which can damage the transistors.

On printed boards excessive heating and leverage must also be avoided otherwise there is a danger that the copper may be lifted away from the board base material.

The checks and test below are designed to cover a variety of faults and repairs, including a few very unusual adjustments which should normally not be required, but these are given for completeness.

3.1 PRELIMINARY CHECKS

1. Check with an Avo that the earth of the mains input socket is connected to chassis.
2. Check that fuses of the correct ratings are fitted.
3. Check that each coax input socket is connected to the associated socket and that the terminations are switched correctly.
4. Apply mains at the appropriate setting of input voltage selector. Apply 625-line resolution pattern signal to the Test input socket and corresponding syncs to the sync input socket. Check the operation of the following controls:

Brightness, Contrast, Picture Size Switch, Width,
Horizontal Shift, Height, Vertical Shift and Focus.

Check that the Red push button selects the Red gun.
Check that the Green push button selects the Green gun.
Check that the Blue push button selects the Blue gun.

5. Check the following PSU output voltages:

+12V	11.4V to 12.6V
+24V	22.8V to 25.2V
+130V	123.5V to 136.5V

On the Line 'B' board set

+240V at B1204 cathode using R1208

Also check CRT heater volts pins 1-14 to be not greater than 6.3V - to be not smaller than 6.1V. Select value of R178 if necessary to bring within limits.

6. Switch ON. Apply 625 Sawtooth and Syncs.

Set brightness and contrast controls to minimum.

Connect EHT meter to C.R.T. anode and chassis.

Set EHT output control (R1024) to obtain 25.0kV. Increase brightness and contrast to obtain 750 μ A beam current. Adjust EHT regulation control (R1031) to obtain 25.0kV. Return to zero beam current, recheck EHT then increase beam current up to 750 μ A noting EHT volts which should deviate from 25.0kV by not more than 0.2kV.

Adjust R1039 so that beam current limits at 750 μ Amp.

Switch OFF. Remove meters and restore monitor to normal.

7. Apply 625 Grid Signal.

Set to small picture size and adjust picture size so that all four corners of video are visible.

Adjust phasing inductor core if necessary, to centre picture information inside the raster. Do not reseal core at this stage.

Set to large picture size and adjust the width so that the outside vertical lines of the grid are coincident with the mask edge. Set the height to about the right aspect ratio. Adjust if necessary focus chain to obtain optimum focus approximately centre of control range (see Appendix 1).

8. Set the vertical and horizontal linearity to obtain a result satisfactory to the eye.

3.1.1 Pincushion

Examine the waveform at left-hand monitor TP551 on the field scan board with CRO at field rate. Set R623 so that the null of the waveform is central and set R613 for minimum ringing after field flyback if necessary.

Set R605 to obtain straight horizontals at top and bottom.

Set R766 (L11 end of field convergence board) to obtain straight verticals at the picture edges.

3.1.2 Purity - Select R.G.B. in turn

- (a) The first check is only necessary if there is cause to doubt the C.R.T. Observe, using a 25 x magnifying lens, the landing of the electrons beam triads relative to the phosphor triads. These latter may be illuminated by a lamp shining on the screen at an angle of about 10° to 15° . Adjust X and Y Purity so that the geometric centre of the electron beam triad is superimposed on the centre of the phosphor triad at the centre of the picture. Note that the electron beam triad is somewhat smaller than the phosphor triad.
- (b) Select RED.
Position the scan coil so that red everywhere in the picture area is unobstructed.
- (c) Check appearance of R, G and B and white in turn.

3.2 POSITIONAL AND MODULATION HUM

1. Select the 625-line or 525-line grid pattern and check that the p-p positional hum at every point in every direction is less than 0.3mm by using a magnifying glass x 10 or x 20. (the horizontal distance between centres of phosphor dots is 0.38 mm. The vertical distance between phosphor dots is 0.315 mm).

Note: DO NOT CONFUSE PHOSPHOR DOTS WITH ELECTRON DOTS.

2. Check that no brightness modulation occurs when 0.4V p-p of 50 Hz sinewave is added to the signal.
3. Check that there is no signal breakthrough visible at zero contrast.

3.3 CHECK OF DEGAUSSING COILS

Magnetise the shadow mask with any small permanent magnet.
Remove magnet. Switch monitor off. Wait a minimum of at least 30 seconds.
Switch monitor on again and check that purity is unimpaired.

3.4 CONVERGENCE (1st stage)

Apply a grid signal to the monitor, set line hold control to centre of hold range. Adjust picture size and centre the picture.

Note 1

The 'Static' convergence controls are set to obtain convergence of the three colours at the centre of the raster. Select Red and Green and adjust 'red static' and 'green static' in turn to superimpose red and green vertically and horizontally at the picture centre. Select monochrome, adjust 'blue static' to superimpose blue on the red and green vertically at picture centre. Adjust 'blue lateral' to superimpose blue horizontally at picture level.

Note 2

The 'Field convergence controls are set to obtain convergence of the three colours up and down the vertical centre line.

Note 3

The 'Line' Convergence is set to obtain convergence along the horizontal centre line.

Note 4

During convergence setting it is necessary to reset the static convergence repeatedly.

Note 5

At this stage the main consideration is to ensure that all convergence controls are working and that the specification requirement is met, i.e. displacement of any two colours anywhere is less than 2 mm.

3.4.1 Switch to the large picture size and adjust the static convergence.

3.4.2 Field Convergence (see note 2 above)

1. Select Red and Green.
2. Adjust R/G Parabola to remove relative vertical bowing.
3. Adjust R/G Parabola BAL and R/G sawtooth BAL so that horizontal lines intercepting the vertical centre line are coincident (note 4 above)
4. Adjust R/G Sawtooth for parallel vertical lines.
5. Repeat foregoing three paragraphs.
6. Select R and B.
7. Adjust B parabola and B sawtooth so that horizontal lines intercepting the vertical are coincident.
8. Adjust B parabola LAT and B sawtooth LAT to obtain parallel vertical lines.
9. Repeat foregoing two paragraphs.

3.4.3 Line Convergence (See Note 3 above)

1. Set B parabola so that the B horizontal centre line matches the R approximately.
2. Select R and G.
3. Adjust R/G parabola BAL and R/G sawtooth BAL to converge horizontal centre lines.
4. Adjust R/G parabola and R/G sawtooth so that vertical lines intersecting the horizontal centre line are coincident.
5. Examine the convergence of horizontal lines near the top and bottom of the picture and adjust R/G keystone in conjunction with R/G parabola BAL and R/G sawtooth BAL to obtain the best overall convergence.
6. Repeat foregoing three paragraphs.
7. Select R and B.
8. Adjust B parabola and B sawtooth to match the horizontal centre lines.
9. Adjust B parabola LAT and B sawtooth LAT to converge the vertical lines intersecting the horizontal centre line.
10. Repeat foregoing two paragraphs.
11. Select R, G, B in turn and then together to recheck purity. Adjust as necessary.

12. At this stage the displacement between any two colours anywhere in the picture should be less than 2 mm.

3.5 LINE SCAN

Increase contrast to normal, rotate line hold clockwise so that the vertical grid line moves off the RHS of the picture. Check that as the line folds back its brightness is reduced and that it vanishes.

3.6 GREY SCALE

1. Apply 625-line Resolution Pattern into Test input.
2. Set brightness to maximum and contrast to minimum. Connect Avo meter on 100V d.c. range between each Cathode and technical earth in turn. Adjust B.L. control R959 on Video Output printed board to give +90V at each cathode.

3.7 PRELIMINARY MONITOR SETTING

1. Apply 625-line Resolution Pattern.
2. Set brightness to zero.
3. Set green video gain to centre of its travel and set contrast control to the step giving closest to 30V video swing at the green CRT cathode, then to set video swing to 30V using green video gain.
4. Set the R, G and B cut-off controls so that the fifth step from the left of the grey scale is near extinction and is grey (i.e. not tinted). Consider the colour of the brightest part of the picture, which must be brought to standard white by adjusting the blue and red video gains. Each adjustment of gain to correct the white will require an adjustment of the appropriate cut-off control to correct the grey. If either red or blue video gain controls requires an adjustment outside the range provided, turn the green video gain in the opposite direction.

When satisfied with the colour at white and grey, increase brightness and check that each step of the grey scale is untinted.

3.8 FREQUENCY RESPONSE (1st stage)

1. Switch to test. Connect oscilloscope using 10:1 probe to green cathode. Adjust contrast control to give 30V of video (i.e. not including syncs). Check that no crushing of the grey scale is evident on the oscilloscope. Remove the oscilloscope. Do not touch contrast control again until after (2). Fix sticker beside contrast knob indicating number of clicks for 30V.
2. Connect 625-line mixed syncs into syncs input. Connect 625-line Resolution Pattern into R.G.B. inputs in turn. Select R.G.B. colour operation. Adjust the brightness control as required and check that the peak whites of each frequency band in the upper row are not darker than the peak whites in the 1 MHz band and that the peak whites of each frequency band in the lower row are not brighter than the peak whites in the 1 MHz band (contrast remains as in (1)). Adjust L951 if necessary to achieve the above performance.

THE FOLLOWING TESTS TO BE CARRIED OUT INSIDE THE DARK AREA

3.9 LINEARITY AND GEOMETRY 625 Grid Pattern

- 3.9.1 Select Green and set to small picture size.
 - 3.9.2 Break syncs (switch to Ext. Syncs and remove ext. sync sigs if necessary). Set free running line oscillator to centre frequency with line hold control (do not adjust the control again during linearity, centering etc., adjustments).
 - 3.9.3 Restore monitor to normal locked picture small size. Readjust phasing inductor core if necessary to centre picture information inside the raster. Seal inductor core if this sealing has been disturbed in previous tests.
 - 3.9.4 Switch to large picture size. Project the linearity slide on to the CRT face normally, centrally, and from such a distance as makes the two outside vertical columns of circles just fit within the mask.
 - 3.9.5 Adjust the picture size, centring, pincushion and linearities to match the slide image so that all points in the picture area A and B of the grid pattern intersections lie within the 2% dia. circles of the slide image. Follow the adjust directions as below. See appendix II for areas A and B.
- 3.9.6
- (a) Connect oscilloscope between efficiency diode anode and technical earth. Lock to line speed and observe waveform as below.

- (b) Select value of capacitors C1178, C1179, C1180 if necessary, to produce ideal waveform, i.e. with point A at centre scan.
If intersection at 'B' add capacitance
If intersection at 'C' reduce capacitance
- (c) Observe Assymetric Non-Linearity on Monitor Tube face.
No cramping should be seen, either right or left.
- (d) Return to the C.R.O. waveform and readjust Capacitor values as in (b) above if incorrect.
- (e) Observe 'S' correction conditions on Monitor tube face. If cramping symmetrically left and right increase boost capacitor C1175 and C1161.
If stretching left and right decrease boost capacitor.
Note: These capacitors must be 1600V working types.
- (f) Switch to small picture size, select C1164 if necessary to produce linearity acceptable to the eye and as close to the requirements of 3.9.5 as possible. Set small picture aspect ratio. Adjust pot R577 if necessary.

3.9.7 Switch to large picture size, check that no ringing is present on line scan and that no flyback lines are evident at the edges of pictures.

3.9.8 Check vertical height, aspect ratio and linearity. Repeat in 3.9.7.

3.10 RECHECK PURITY

1. Select Red. Make final adjustments to X-Y controls if necessary.
Degauss if necessary.
2. Check appearance of R, G and B, and white in turn. Purity must be at optimum at this stage.

3.11 RECHECK CONVERGENCE 625 line grid

Select R, G, B. Recheck convergence. Repeat the whole of Section 3 if necessary. This time the following standard must be obtained:

Maximum displacement vertical or horizontal between any two colours in area A to be less than 0.54 mm
area B to be less than 0.8 mm
area C to be less than 1.1 mm

(see appendix II for areas A, B and C).

3.12 RECHECK FREQUENCY RESPONSE 625 Resolution Pattern

1. Reset contrast control to obtain 30V of Video as indicated by sticker alongside knob (see 3.8.(1)).
2. Adjust the brightness control as required. Select R.G.B. and white in turn. Adjust L951 and C953 only if necessary, to achieve the full requirement as outlined in 3.8(2).
3. Remove sticker. Reseal L951 core if sealing disturbed in previous tests.

3.13 DECODER

1. If a decoder is fitted apply the appropriate encoded signal at a level of 0.7V p-p. Check the video output swing at the cathodes of CRT is 30V min, also check that no crushing of the signal is evident.
2. Check the appearance of the picture. Switch to monochrome. Check that the picture appears to be truly monochrome. Apply the resolution pattern to the decoder input. Check that on colour and monochrome the frequency response etc. appears satisfactory. There should be no changing from monochrome to colour.

3.14 LINE AND FIELD HOLD

1. Check that line hold is obtained over at least 60% of the range of the control. Check that field hold is obtained over at least 60% of the range of the control.
2. Check that interlace is better than 45:55 throughout the field hold range,
3. Check that the synchronisation of the picture is unimpaired and check that no brightness modulation hum is present:
 - (a) with the addition to the video signal of 50 Hz sinewave of 0.4V p-p amplitude.
 - (b) when passing the video signal through a capacitor of $1\mu F$.

3.15 RECHECK FLYBACK

On 625-lines at low contrast check that no flyback is evident at edges of picture and that no ringing is present on line scan.

3.16 SOAK TEST

Operate all monitors for 4 hours with normal signal and nominal main voltage applied after any major repairs.

APPENDIX I - ADJUSTMENT OF FOCUS RESISTOR

The resistor to be fitted must be Philips 1 watt type CR68. The value will be around $680\text{k}\Omega$ for optimum focus in the centre of the control range. Measure voltage drop across the resistor (Avo 1000V range). If the voltage exceeds 730 volts the value of resistor must be made up of 2 resistors in series.

APPENDIX II

Area A is an ellipse of minor (vertical) axis equal to picture height, and major axis equal to 0.8 of picture width.

Area B is an ellipse of minor axis equal to picture height and major axis equal to picture width.

Area C is outside Area B.

SECTION 4

SETTING UP PROCEDURES

4.1 GENERAL CHECKS

4.1.1 Power Supply

1. Set the two carousels on rear panel for the required mains voltage. Check that VL1 and VL2 are 3.15A rating for 220/234V working, or 6.3A for 110/117V working.
2. Set 0V link on rear panel to connect black and yellow terminals for floating 0V or to connect black and green for capacitive earth.
3. Check the 12V stabilised supply. The output voltage is to be between 11.8V and 12.6V under local conditions. R178 may be replaced if necessary by a different valve.
4. Check the 24V stabilised supply. The output voltage is to be between 22.8V and 25.2V under loaded conditions. R163 may be replaced if necessary by a different value to bring within the limits stated.

4.1.2 Field Scan and Pincushion

1. Field Hold

Set 50/60 Hz system switch to required system and set hold control on monitor front and drawer (R558) to the centre of the range over which synchronism is obtained. Ensure that picture locking is satisfactory.

2. Field Amplitude

Switch to large picture size and adjust R576 for correct aspect ratio of 4:3.

Switch to small picture size and adjust R577 for correct aspect ratio.

(For R576, R577 see circuit 0178).

3. Linearity

Correct the linearity, if necessary, of the top relative to the bottom of the picture by adjustment of R580.

Correct the linearity of the centre area of the picture relative to the top and bottom by adjustment of R588.

(for R580 and R588 see circuit 0178).

4. Pincushion

Examine the waveform on monitor point TP551 with an oscilloscope trace locked at field repetition frequency (for TP551 see Field Scan Module Circuit 0178).

Set R623 so that the null point of the waveform envelope is central.

Set R613 for minimum ringing after field flyback (ignore 100 Hz hum).

Set R605 to obtain straight horizontals at top and bottom of picture.

Set R766 on field convergence board (see circuit 0180) to obtain straight verticals at the picture edges.

Note: R623, 613, 605 are shown on circuit diagram 0178 for the Field Scan and Pincushion Module.

4.1.3 Sync Process (See Circuit 0463)

1. Polarity of External Sync

For negative sync input connect link across R456 and also connect link from RLA(1) to collector circuit of TS451. No link should be across R454.

For positive sync input remove link from across R456 and connect across R454. Connect link from RLA(1) to the emitter circuit of TS451.

2. Amplitude of External Sync

Set link in the emitter circuit of TS451 for the required range of input amplitude, 0.5V to 3V or 1.5V to 6V if necessary.

3. Line Hold

Connect video signal to Test input socket. Remove syncs. (switch to external syncs and remove external sync signal if video signal is composite). Set free running line oscillator speed with hold control R553 so that picture is moving slowly sideways across screen. Restore syncs.

4. Line Phase

Set line hold control as in 3 above. Switch to small picture size and adjust L452 core to centre the picture information inside the raster.

5. Brightness Pulse Width

Check that the mean width of the brightness pulse as measured on monitor point TP459 is $2.2\mu\text{s} \pm 10\%$. Value of R495 may be selected if necessary to bring within limits stated.

6. Clamp Pulse Width

Check that the mean width of the clamp pulse as measured on monitor point TP456 is $1.5\mu\text{s} \pm 10\%$. Select value of R507 if necessary to bring within limits.

4.1.4 Line Output Unit

1. Screen Stabiliser

Adjust R1208 to obtain +240V at the cathode of B1204 - see circuit 0170.

2. Linearity

Check with an oscilloscope on the anode of B1153 that the linearising sawtooth finishes at approx the centre of the scan period. If necessary adjust capacitors C1178, C1179, C1180 for value to achieve this.

If crushing occurs symmetrically outwards from centre, increase capacity of C1175 and C1161.

If stretching occurs symmetrically outwards from centre, increase capacity of C1175 and C1161.

3. Amplitude and Shift (Controls in Front Drawer)

Adjust so that with picture size switch set to large the picture width just fits the mask.

4.1.5 E.H.T. Unit (See Circuit 0170)

1. Output Voltage

Adjust R1024, if necessary, to obtain 25kV when the cathode ray tube beam current is zero. 25kV must be measured on an electrostatic voltmeter.

2. Regulation

Adjust R1051, if necessary, for minimum change in picture size when the beam current of the CRT is changed from 0 to 750 μ A.

3. Beam Current Limit

Connect voltmeter (20,000 Ω /volt) across R1025. Set R1039 so that voltage is limited to 5.5V for 19" CRT or 7V for 25" CRT when brightness and contrast controls are operated.

4.1.6 Video Output Amplifiers (See Circuit 0183)

Black Level

Turn contrast control to minimum and brightness control to maximum. Both controls are on monitor front panel.

Control voltmeter between cathode of CRT and 0V line. Set R959 to give 9V at the cathode.

Return controls to normal position.

4.1.7 Frequency Response

Adjust L951 on the video output module - see circuit 0183, for flat response to 5 MHz. Minimum for the output amplifier.

Maximum measured deviation from response at 1 MHz is ± 0.5 dB.

4.2 SETTING UP PROCEDURE FOR PURITY, CONVERGENCE AND GREY SCALE TRACKING

4.2.1 Purity

- (a) Allow the set to run at a beam current of approximately $750\mu\text{A}$ for 15 minutes with a plain white raster.
- (b) Using a microscope or other suitable device, of magnification $\times 20$, examine the centre of the screen and adjust the X and Y purity controls until the centre of the illuminated RGB triangles coincides with the centre of the RGB phosphor dot triangles.
- (c) Switch on the Red beam only. Adjust the position of the deflection coils until correct beam landing is achieved at the picture edges.
- (d) Check Blue and Green rasters for optimum purity in the same manner. Lock deflection coils. Check with White raster only.
- (e) Recheck picture centering, and Static convergence - see 4.2.2(b).

Note: Final adjustments for the white area appearance are carried out in 4.2.2(f) below.

4.2.2 Convergence

- (a) A medium luminance cross hatch grid pattern is recommended for the test signals. Set line hold to centre of locking range. Set to large picture size and centre within frame.
- (b) Static convergence is achieved by adjusting the three radially acting controls R, G and B, and one lateral control (blue) to obtain coincidence of Red, Green and Blue in the centre of the picture. First select R and G and adjust R static and G static in turn to superimpose R and G vertically and horizontally at the picture centre. Then select monochrome and adjust blue static to superimpose blue on the red and green vertically. Finally adjust B lateral to superimpose blue horizontally at picture centre.
- (c) Dynamic Vertical Convergence controls are set to obtain convergence of the three colours up and down the vertical centre line.

Adjust controls as below, resetting the static convergence controls as necessary for optimum result.

Select Red and Green.

Adjust R/G Parabola to remove relative vertical bowing.

Adjust R/G Parabola Balance and R/G Sawtooth Balance so that horizontal lines intercepting at the vertical centre line are coincident.

Adjust R/G Sawtooth for parallel vertical lines.
Repeat the above adjustments. Select R and B.
Adjust B Parabola and B sawtooth so that horizontal lines intercepting at the vertical are coincident.
Adjust B Parabola Lateral and B Sawtooth Lateral to obtain parallel vertical lines. Repeat adjustments for R and B selection.

- (d) Dynamic Horizontal Convergence controls are set to obtain convergence along the horizontal centre line.

Adjust controls as below, resetting the static convergence controls as necessary for optimum results.

Adjust B Parabola so that the B horizontal line matches the R approximately. Select R and G.

Adjust R/G Parabola Balance and R/G Sawtooth Balance to converge the horizontal centre lines.

Adjust R/G Parabola and R/G Sawtooth so that the vertical lines intersecting the horizontal centre line are coincident.

Examine the convergence of horizontal lines near the top and bottom of the picture and adjust R/G Trapezium in conjunction with the Balance controls for R/G Sawtooth and R/G Parabola to obtain the best overall convergence.

Repeat adjustments from selection of R and G. Select R and B.

Adjust B Parabola and B Sawtooth to match up the horizontal centre lines.

Adjust B Parabola Lateral and B Sawtooth Lateral to converge the vertical lines intersecting at the horizontal centre lines.

Repeat last two adjustments.

- (e) General

The sequence of adjustments is not important, but the pairs of controls should be adjusted simultaneously, i.e. Red/Green ST with Red/Green P, Blue ST with Blue P, the usual sequence is:

- (i) Red/Green Static
- (ii) Red/Green Vertical
- (iii) Red/Green Horizontal
- (iv) Blue Static Radial
- (v) Blue Static Lateral
- (vi) Blue Vertical
- (vii) Blue Horizontal

Interaction within the Convergence Unit means that the procedure has to be repeated until satisfactory conditions are obtained.

(f) White Point and Grey Scale Tracking

- (i) A test signal containing a sequence of steps (staircase and waveform) from black to white is used for this setting.
- (ii) Set Master Brightness Control on Front of monitor fully clockwise.
- (iii) Adjust R, G and B Brightness controls in front drawer unit to be just above cut-off in the black areas.
- (iv) Set R, G and B Video Gains in front drawer unit to 80% - 90% of fully clockwise position.
- (v) Adjust any one or two controls in an anticlockwise direction to achieve the desired White Point (Hue) in the peak white areas of the test signal, i.e.:

If the White area is:	Red	Reduce Red gain
	Blue	Reduce Blue gain
	Magenta	Reduce Red and Blue
	Cyan	Reduce Blue and Green
	Yellow	Reduce Red and Green

- (vi) Set the Master Brightness Control on monitor front panel anticlockwise to 20° - 30° and adjust the R, G and B Brightness controls to obtain the same Hue as in (v) above in the dark grey areas of the test pattern. The black areas should be just cut off.

4.3 PROCEDURE FOR CHECKING PERFORMANCE OF PAL DECODERS
EL8618 WHEN FITTED IN MONITOR ET9954

NOTE

This method in no way replaces the setting up procedure laid down in the Test Specification but is intended to allow circuit performance to be checked and any minor adjustments thought necessary to be made.

Signal Required Composite coded (PAL) colour bars 1V p-p 100%
Luminance to 100% Saturation

Oscilloscope 10 Mc/s bandwidth, X sensitivity 1V/cm with a low capacitance probe.

4.3.1 Luminance Gain

1. Monitor decoder input (C113 negative end). Note amplitude of white bar.
2. Monitor blue channel output (Pin 1). Adjust contrast (R123) if necessary to give unity gain for white bar, i.e. 1V peak to peak.

Check white amplitudes of Red (Pin 21) and Green (Pin 18) channels. The maximum amplitude difference between the two channels shall be less than 1% of Blue channel output at pin 11.

4.3.2 Chroma

With crocodile clips connect collector (case) of TS804 to 0V line.

1. Monitor the junction of R209, C204. This shall be a negative going pulse of 1.4 ± 0.3 V p-p and of width 4.5 ± 0.1 μ s. Adjust R221 (set gate width) if necessary to alter pulse width.
2. Monitor link 'F'. Adjust chroma gain control if necessary to give about 1V p-p burst waveform.
3. Monitor the junction of C801, C802. Check that a half line frequency sine wave is present. Amplitude to be greater than 1.5V p-p (this sine wave may be slightly distorted).
4. Connect +V monitor point to scope Y input and +U monitor point to scope X input.

The display will be similar to a vectorscope display. All colour points should be single dots or two dots in very close proximity. On units fitted with delay/simple relays, switch from delay to simple operation. The amplitude and form of the display should not alter.

5. If there is any doubt as to the accuracy of the decoder setting up with respect to this display, the following procedure extracted from the Test Specification should be followed:

(N.B., If no relay fitted, short test points e to g for Delay or e to c for simple).

Set Decoder for Delay operation.
Set R912 to mid-position.

Procedure

- (a) Adjust core of T201 to give maximum amplitude display.
- (b) Adjust R657 (180° switch balance) for best dot alignment in Y directions on the oscilloscope display.
- (c) Adjust core of T902 for best coincidence of two dots along centre axis (X direction) of display.
- (d) Adjust core of T901 for best overall dot coincidence.
- (e) Switch to Simple. Adjust core of T201 for best dot coincidence.
- (f) Adjust R906 (gain compensate) so that vector amplitudes of displays for Simple and Delay operation are equal.
- (g) On Delay readjust cores of T901, T902 for best dot coincidence as in (c) and (d).
- (h) On Simple adjust core of T504 for best dot coincidence. Readjust core of T201 for best dot coincidence.

This procedure may require repeating in parts in order to obtain the correct display.

6. Remove oscilloscope X input.

Monitor Blue output. Adjust core of L103 if necessary for minimum subcarrier. Subcarrier should be at least 30 dB down on i/p value, with unity luminance gain, i.e. with 1V peak to peak as set up in 4.3.1.

4.3.3 Chroma Gain

1. For Decoders not fitted with Remote Chroma Gain Facility

Adjust R125 (chroma gain) for equal amplitude blue bars. Monitor green o/p and adjust R651 (set gain) for correct green bar pulse.

2. For Decoders fitted with Remote Chroma Gain Facility

Attenuate signal by 3 dB.

Turn monitor chroma gain to approximately mid-position. Adjust R125 on decoder for equal amplitude blue bars. Monitor +U and note signal amplitude. Readjust R125 so that signal amplitude varies by at least ± 3 dB from minimum to maximum setting of remote chroma control. Set monitor chroma for equal blue bars. Adjust R651 (set gain) for correct green bar pulse. Check red o/p.

Remove link from TS804 to OV line.

With i/p signal attenuated by 3 dB adjust R307 (colour killer) so that signal is only just visible.
